

Leonardo's investigations into the workings of the human body led him far beyond the frontiers of Renaissance medicine. His notebooks were filled with unique observations on the skeleton, the digestive system, the brain, and the heart.

Such discoveries could have revolutionized medical science at the time. However, none were published, either during Leonardo's life or for centuries after his death. This greatly limited their influence, but they remain

amazing achievements.

For such a famous artist, it may seem odd that Leonardo completed only a handful of paintings. Some of his reluctance to finish projects came from having a curious mind that was almost too eager to embrace new things.

This statue of Leonardo was sculpted by Luigi Pampaloni in the 1800s. It is in the courtyard of the Uffizi Gallery, Florence.
