

Amphibians

Breathing

Frogs breathe through their skin when underwater, but use their lungs on dry land.

Amphibians are animals like frogs and newts, which live partly in freshwater and partly on land. They lay their eggs in water.

Growing up

Amphibians change their shape as they grow. This is called metamorphosis.

1 Large groups of frog eggs are called spawn.

2 Each egg grows into a tiny tadpole that takes in air through its gills.

3 The tadpole grows legs and loses its tail.

4 The grown-up frog breathes with lungs.

Strong back legs for hopping and swimming

Damp skin

Nostrils

Large eyes look for insects.

Webbed feet move like paddles in the water.

Frog

The red-eyed tree frog is one of 4,000 different amphibians. Its body is well adapted to life both in water and on land.

Did you know?

Frogs have sticky tongues.

They flick them out to snag prey.

Deadly color

Some amphibians, like this frog, are poisonous. Their bright colors warn other animals not to eat them.

Golden poison-arrow frog

Other amphibians

Marbled newt

Newts have a long, thin body like a lizard.

Ornate horned toad

Toads look like frogs, but have bumpy skin.

Fire salamander

Salamanders spend most of their time on land.
