

Animals

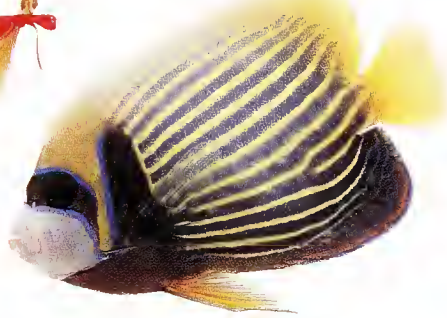

Mammals, such as humans, live mainly on land. Only a few live in the sea.

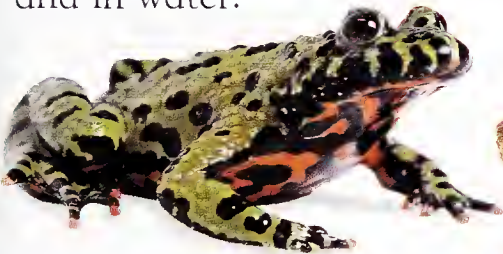

There are more than ten million different species of animals in the world. Scientists have divided them into two main groups.

Vertebrates

Fish live in the world's rivers, lakes, and oceans. They take in oxygen through their gills.

Amphibians, such as frogs and toads, live both on land and in water.

Reptiles, such as snakes, lay eggs on land and have dry, scaly skins.

Birds are animals with beaks, feathers, and wings. Most of them can fly.

Vertebrates

Vertebrates are animals with backbones. They are split into five main groups.

Invertebrates

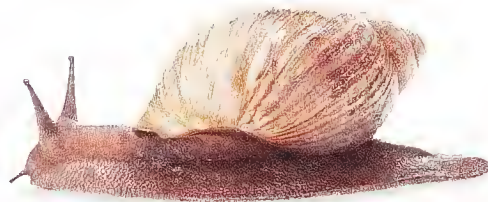

Starfish and sea urchins belong to a group of animals with spiny skins.

Octopuses and squid have soft bodies. They are related to mollusks, but do not have a shell.

Mollusks, such as snails, have hard shells to protect them from enemies and sun.

Insects, such as beetles, have a hard outer skeleton.

Crustaceans, such as crabs, shed their shells when they grow too big for them. A new shell grows underneath.

Invertebrates

Invertebrates are animals with no backbones. Many have hard shells or a tough outer skeleton to protect them.

Did you know?
Most invertebrates are so tiny they can only be seen under a microscope.
