

At 5,500°C (9,930°F), Earth's inner core is made of a solid iron-nickel alloy

The outer core is liquid, and is believed to generate Earth's powerful magnetic field

The mantle is the thickest layer in our planet's interior. It churns about slowly, causing the rigid crust above to move.

Earth's constantly-shifting crust is home to violent earthquakes and destructive volcanoes

LIFE-GIVING LIQUID

Water drives life. It helps to support the chemical reactions that enable life to thrive: our bodies are made up of 60 per cent water. Water is rare on the other planets, which are either too hot or too cold – it is only in the “Goldilocks Zone” (where the temperature is neither too hot nor too cold) around our Sun that liquid water can exist.

DATA FILE

TIME TO ROTATE ONCE: 23.9 hours

YEAR: 365.26 days

NUMBER OF MOONS: 1

SURFACE TEMPERATURE:
-93 to 71°C (-135 to 160°F)
