

Liquid hydrogen
lies below
Saturn's clouds

MIGHTY TITAN

Saturn has at least 62 moons – the biggest being Titan, which is larger than Mercury. In 2005, the Huygens probe penetrated the moon's thick clouds and landed on its frozen surface. Titan has huge lakes of ethane and methane.

The gas giant's core
may be solid or liquid,
or a mix of both

Compressed hydrogen,
behaving like liquid
metal, surrounds
the core

Saturn's **density**
is so low that,
if it were put
in an ocean, it
would float.
