

Neptune's hot core may be surrounded by an ocean of liquid diamonds

Most of the planet's mass lies in the mantle, which is a layer composed of a deep ocean of water, ammonia, and methane

ICE-COLD TRITON

At 2,700 km (1,680 miles) across, Triton is Neptune's biggest moon. It is one of the coldest places in the Solar System. It has geysers that erupt plumes of nitrogen and dust into space. Triton orbits in the "wrong" direction, moving the opposite way to Neptune's rotation. In the future it may collide with the planet, disintegrating into a brilliant set of rings.

One of Neptune's five faint rings, made mostly of dust

The Great Dark Spot, a dramatic cloud feature, spotted by Voyager 2 when it swung by the planet in 1989, disappeared quickly, like most of Neptune's weather features

Winds on Neptune reach over 2,000 kph (1,240 mph), the **fastest in the Solar System.**
