

ANDRIJA MOHOROVIČIĆ

Croatian geophysicist • 1857–1936

Around a year after Andrija installed the seismographs, an earthquake struck the nearby Kupa Valley.

As a child, Andrija flexed his brilliant brain by learning languages. He mastered four by the time he was 15, and later learned four more! In college, he studied math and physics, and he was later made director of Croatia's main observatory in the capital city, Zagreb. Andrija decided to install seismographs—instruments that detect the vibrations caused by earthquakes—at the observatory. It was a decision that would lead to a groundbreaking discovery. On October 8, 1909, a large earthquake struck Croatia's Kupa Valley, just 24 miles (39 km) from the Zagreb Observatory. Andrija studied the readings taken by his new seismographs, and those from other stations, and noticed something strange.

Andrija developed a method of locating the epicenter—the spot directly above where an earthquake starts.
