

Vibrations that shook the Earth

Some of the vibrations had arrived at Zagreb far sooner than expected. Somehow, they had sped up as they traveled deep underground! Andrija realized that the vibrations must have traveled through very different types of rock—an outer layer (now called the crust) and an inner layer, where waves could travel much faster (now called the mantle).

Andrija estimated that the Earth's crust is around 30 miles (50 km) thick. He was close to the truth—today's instruments show that the boundary between the crust and the mantle lies about 22 miles (35 km) underground. It has been named the Mohorovičić discontinuity, or "Moho" for short, in honor of the way Andrija's work completely changed the way we understand our planet.

Meteorology

At the beginning of his career, Andrija taught sailors about weather and ocean science at a nautical school. He was fascinated by ships because his father worked on a shipyard, so he had found a job that combined ships and science! Here, he set up his first weather station.

Andrija helped to persuade governments to build earthquake-proof buildings.

The top two layers of rock were later named the crust and mantle. The boundary between them was named after Andrija.

Vibrations traveling through the mantle reached Zagreb first.

the ground lie different layers of rock.
