Dog

Procedural memory

Endel developed a way to use positron emission tomography (PET) scanning to see memories in action.

Making memories

How do people store words, facts, skills, and memories and recall them exactly when needed? Endel designed experiments to find out more. One of his experiments involved 900 school students. It showed that different parts of the brain are involved in storing and retrieving memories. Both processes are needed for us to remember something. Next, Endel explored memories themselves and defined three different types.

Studying the mind is very difficult. We cannot see a brain from the outside, and it's dangerous to start poking around inside! As medical technology improved, Endel found ways to safely watch the brain at work. This helped him prove that different areas of the brain are involved in storing and retrieving memories.

A single human brain may be able to store a quadrillion bytes of data—as much information as is on the entire Internet!
