

It's all relative

Albert's most famous idea is relativity. He realized that Newton's simple laws can't always explain how things move. For example, imagine a frog hopping up and down on a rolling skateboard. A person standing on the ground looking at the frog side-on would see the frog move up, down, and sideways. But, a person standing on the skateboard would only see the frog moving up and down. The way the frog seems to move is relative, or related, to where we are as we observe it.

Amazingly, Albert realized that even time can seem to go faster or slower, depending on where you are and how you are moving when you measure it!

Every object in the universe bends, or warps, space-time around it—even frogs! The more massive an object is, the more it bends space-time.

When a planet, a spacecraft, or a beam of light travels through this warped space-time, its path is bent, too. This is the effect that we call gravity.

$$E = mc^2$$

Albert wrote the equation $E = mc^2$ to show how energy (E) and mass (m) are really two different forms of the same thing!

The "c" stands for the speed of light.

After Albert died, scientists studied his brain. It had more connections between the left and right sides than usual.
