

Pull

Pulls also make things move. The harder you pull, the faster an object travels. When you throw a ball into the air, a pulling force called **gravity** makes it fall to the ground.

Without the pull of Earth's gravity, if this apple broke off from its branch, it would drift off through the air!

Gravity

Gravity is a pulling force between all objects. Bigger objects have more gravity. Planets, such as Earth, have really strong gravity.

We only notice air when the wind blows!

Friction

When one surface moves over another, a sneaky force called **friction** tries to slow it down. The rougher the surfaces, the more friction between them.

Rough, bumpy surfaces

Bumps snag on each other.

Lots of friction

Smooth surface doesn't snag.

Objects slide more easily over each other.

Not much friction

Air resistance

A force called air resistance acts on things moving through air. It tries to resist the pull of gravity on falling objects. That's why a parachute drifts safely down to the ground.
