

Sound

Sound is a form of energy produced when objects vibrate, or move rapidly to and fro. The vibrations, called sound waves, spread out through the surrounding air.

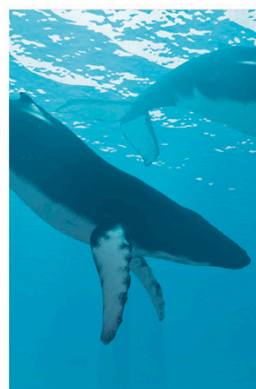

Sound travels

Sound needs a material to move through, such as wood, metal, brick, air, or water. In air, sounds travel at 1,080 ft (330 m) a second, but they travel more than four times faster in water.

Echoes

Shout "Hello!" in a cave, and the word bounces off the cave walls and comes back to your ears. The sound that bounces back is an echo.

Water

Sounds travel farther, as well as faster, in water than in air. Humpback whales call to each other with "songs" that can be heard 100 miles (160 km) away.
