

WORLD *of* PLENTY

Every square inch of our planet is occupied by some form of life. From the highest mountaintops to the depths of the oceans, something has found exactly what it needs to survive and make a life there.

WHO LIVES WHERE

Although organisms are found everywhere on Earth, more species live in tropical regions than at the poles. Climate and abundance of food are the main factors affecting how many and what type of species live there.

CLIMATE

Arctic

It's hard for plants and fungi to survive the cold, so animals and bacteria are the main species.

Northern hemisphere

Warmer temperatures and more rain mean more plants, fungi, and a wider range of animals.

The equator

The warm, wet, sunny tropics are attractive to plants, which make them an ideal habitat for all sorts of living things. These areas have the most species.

Southern hemisphere

A wide range of plants and animals live here, and its oceans are full of species.

Antarctic

There are few plants, but animals and birds use the firm land under the ice as a breeding ground.
