

SEED DISPERSAL

Once the flowers have been fertilized the seeds start to form. When they're ripe the plant needs to disperse them as far as possible so they have the best chance to grow. Some are carried by the wind or water, and some simply fall off and roll away. Others explode or catapult their seeds over long distances. Animals also help by eating or burying seeds, or carrying them on their fur.

By eating and burying nuts and seeds, I help new trees to grow.

IDENTICAL COPIES

A number of plants can reproduce without seeds. They do this by using their stems, roots, or leaves to make identical copies (clones) of the parent. This method is useful when the conditions are not ideal for seeds to sprout.
