

Comet McNaught
On August 7, 2006, Robert McNaught discovered a comet that within months became the brightest in Earth's sky for more than 30 years. In January 2007, when at its closest to the Sun, it had a large head and spectacular tail and was impossible to miss in the southern sky.

Comet Tempel 1
This image was taken in 2005 by the *Deep Impact* spacecraft 67 seconds after the craft released a missile to impact the nucleus. Light from the collision shows a pitted, ridged surface.

Comet Borrelly
The bowling-pin-shaped nucleus of Comet Borrelly was imaged by the *Deep Space 1* spacecraft in 2001. It is 5 miles (8 km) long and orbits the Sun every 6.9 years. Color has been added to highlight dust and gas jetting out of the nucleus.
