

If it was possible, it would take a jumbo jet about 400 years to fly from Earth to Neptune.

Neptune

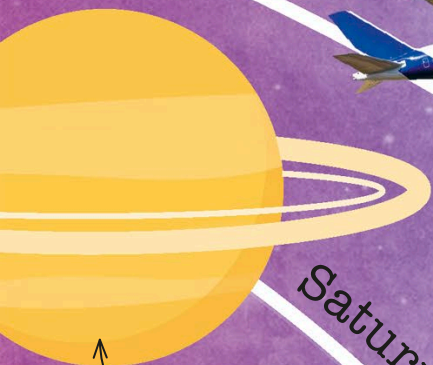

Neptune is the furthest planet from the Sun, which makes it freezing cold!

The Kuiper belt is a very distant part of the Solar System. It is the home of icy dwarf planets and comets.

Kuiper belt

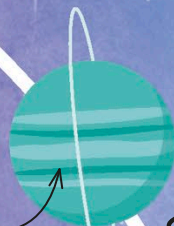

Pluto

Pluto is the largest dwarf planet in the Kuiper belt.

Saturn

Saturn has more than 50 moons. It is most famous for its rings, which are made of lumps of ice and rock.

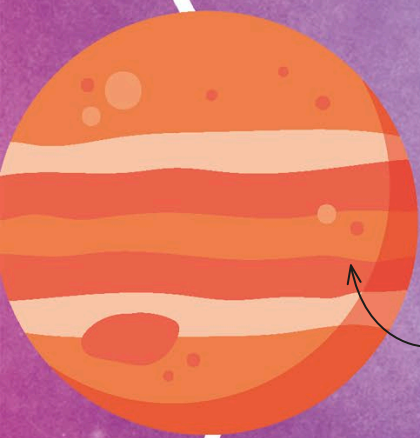

Uranus

Unlike the other planets, Uranus spins on its side. This might have been caused by a collision with an Earth-sized object.

Launched in 1977, the space probe Voyager 2 reached Neptune in 1989.

Jupiter

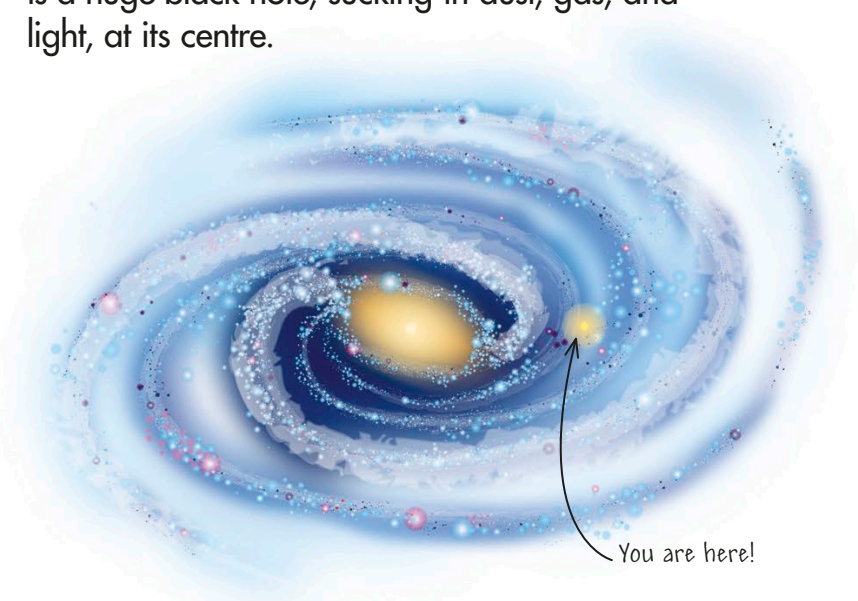

Jupiter is by far the largest planet in our Solar System. It is made mostly of gas and has more than 60 moons orbiting it.

Jupiter is so huge that all the other planets in the Solar System could fit inside it.

Milky Way

Our Solar System is part of a galaxy called the Milky Way. It is spiral in shape and has more than 100 billion stars. Scientists think there is a huge black hole, sucking in dust, gas, and light, at its centre.
