

Solar flares

Gigantic explosions on the Sun's surface blast energy outwards. These are called solar flares.

Sunspots

Dark, cooler patches that develop on the Sun's surface are known as sunspots. They often appear in pairs and last a few weeks.

The surface of the Sun is a sizzling hot $6,000^{\circ}\text{C}$ ($11,000^{\circ}\text{F}$). That's 30 times hotter than an oven!

At the Sun's core, temperatures soar to around 15 million $^{\circ}\text{C}$ (27 million $^{\circ}\text{F}$)!

Our super Sun

The Sun is our nearest star and it sits at the centre of our Solar System. It is a massive ball of burning gases, mostly hydrogen and helium, which produces an enormous amount of energy.
