

Gases

Gases are all around us – the air is made up of gases. A gas will fill any container and can be squashed. Most gases are invisible.

Gas molecules are spread out and move about very quickly.

Condensation

When a gas cools, it turns into a liquid. This is condensation. If you breathe out water vapour onto a cold surface, such as a window, it condenses into water droplets.

The particles in a solid are packed together so tightly that they make a fixed shape.

Evaporation

When they are heated, molecules jump out of liquids and become gas. This is called evaporation.

Solids

Solids feel firm and are hard to squash. This book is solid, and so are things that you can hold, wear, or sit on.

Freezing

A liquid freezes to a solid at a temperature called the freezing point.

Melting

When a solid heats up, its particles vibrate. When it reaches a temperature called the melting point, its particles break free and become liquid.
