

*The sundew tricks and
eats insects as large
as dragonflies and
butterflies.*

Sundew

Midges and flies: beware! The sundew has a deadly secret... a taste for meat. The red hairs on its leaves look pretty, but they are traps. All the hairs have a drop of clear goo on the end, and when an insect lands on them it discovers the liquid is also a sticky glue. The more a poor insect wriggles, the more stuck it becomes. Finally, it dies. The sundew rolls its leaf up, with the insect trapped inside like a sandwich filling, and digests its meal.

Sundews grow in bogs and wet ground. Here, the soil has little food in it. By capturing and eating insects, these carnivorous plants get the extra nutrients they need.
