

The first bumblebees lived high in the Himalayan mountains where the air is very cold, so they grew cosy fur coats. They are so good at staying warm that they can even live in the freezing Arctic. Bumblebees are incredibly active insects and can visit several thousand flowers a day. As they weave their way between blooms, their rapidly beating wings make the familiar buzzing sound that means a bumblebee is near.

When a buzzing bumblebee visits a flower it shakes itself to make pollen fall onto its hairy body.

The bee sweeps the pollen into special baskets on its back legs, and takes it back to the nest for the baby bees, called larvae, to eat.
