

Iris scans are
more accurate
than taking
fingerprints
because they can't
be duplicated.

Fingerprint scan

Fingerprint scanners work by capturing the pattern of ridges and valleys on a finger. The data is compared against a database of other fingerprints to find the closest match and identify the individual.

Facial recognition

From the distance between the eyes to the length of the jawline, every face has unique features. Facial recognition systems take these measurements and compare them against a database of face shapes. A positive match confirms the identity of the person.

Speech recognition

Speech recognition systems compare the sounds of our voice against a database of word sounds to understand how we normally sound when using words in a sentence. This allows the user to command smart devices to carry out certain tasks by speaking to them.
