

SAFE DRIVING

CRASH TESTING

To determine how safe a new vehicle is, engineers conduct crash tests that mimic what happens in real-life accidents. During a collision, a moving car comes to a sudden stop, but its passengers have the same momentum as before and continue moving, which can result in injury. By collecting data, crash tests help minimize the risk of injury and improve the safety features of a vehicle, such as airbags and seatbelts.

TEST DUMMIES

Life-size dummies are used in a crash test. They come in many shapes and sizes—adult, child, male, or female—and match the way people move on impact. Each dummy contains more than 130 sensors that record the chances of injury during different crash scenarios, providing data to improve car safety.

During a crash test, vehicles crash at an average speed of **35 mph** (56 km/h).
