

The background of the page is a watercolor-style illustration. At the top, a large, reddish-brown dinosaur head (Argentinosaurus) is shown in profile, looking towards the left. Below it, a long, yellow and green flying snake is depicted in mid-air, its body curved into a loop. At the bottom, a large, brown pterosaur is shown in flight, its wings spread wide. The overall color palette is warm, with earthy tones and soft, blended colors.

Huge size
No real creature is big enough to wrap itself around the world like some dragons, but Argentinosaurus, the largest dinosaur ever discovered, grew to be up to 115ft (35m) long!

Wingless flight
Many Asian dragons can fly even though they don't have wings. It seems impossible, but the paradise flying snake comes close, and is able to glide short distances between trees.

Winged flight
It's likely that most winged dragons would be too heavy to fly. However, the same was once thought about pterodactyls until it was discovered that they had hollow bones like birds.
