

Air circulation

Improving airflow helps cool high-up plants so they don't dry out so quickly and generally helps prevent dampness, reducing the chances of rot and disease.

Heartleaf philodendron (see pp.114–115)

Aim to position plants within easy reach, where you can access them for regular care

Cape primrose (see pp.130–131)

Pink quill (see pp.132–133)

Heat The heat from radiators can dry plants out and burn them, while temperature fluctuations can also cause distress, so choose tough, drought-loving plants such as cacti and succulents for hot spaces.

Blue torch cactus (see pp.116–117)

Tiger aloe (see pp.40–41)

Light levels Generally, the darker the foliage, the darker the position a plant can tolerate, as this tends to mean a higher chlorophyll content to better extract light. Most plants, however, like a spot with bright yet indirect light.
