

DENSITY TOWER

Make an eye-catching tower in a glass by layering colored liquids one above another. It looks like a magic trick, but it works because liquids of different densities, such as oil and water, don't mix together. In this experiment, the most dense liquids form the bottom of the tower and the least dense float on top. You'll find most of the things you need for your tower in the kitchen pantry. So, let's get building!

Oil floats at the top because it is the least dense of all the liquids used in the tower.

A ping-pong ball has a low density because it is filled with air. Drop it in the tower and see what happens.
