

A large, detailed illustration of a single raindrop acting as a lens. A white line representing a ray of sunlight enters the top-left of the drop at point 2. Inside the drop, the ray splits into a spectrum of colors (red, orange, yellow, green, blue, purple). At point 3, the light reflects off the back surface of the drop. At point 4, the light exits the bottom of the drop, having spread out into a wide rainbow. The background is a soft-focus sky with many smaller raindrops and stylized clouds at the top.

2 Splitting up

As a ray of sunlight enters a raindrop, it bends and spreads into rays going in slightly different directions. These rays now appear as different colors.

3 Bouncing back

The light bounces (reflects) off the back of the raindrop. The light shines backward and downward toward your eyes.

4 One of many

As the light leaves the raindrop, the rays spread out more. Light splitting into colors happens in every one of the millions of raindrops in the sky. Together, the drops make a multicolored rainbow.
