

## 1 Spin and lift

The main rotor turns hundreds of times every minute, in the direction of the green arrows. This creates a force called lift, which raises the helicopter into the sky.

## Search equipment

Radar, satellite navigation, and night-vision equipment are used to search for objects, especially at sea.

## Rescue service

This search-and-rescue helicopter has a stretcher that can be lowered to pick up injured people.

## Taking control

The pilot flies the helicopter by using two separate hand controls and two foot controls.

## Twin rotor Chinook

The Chinook helicopter has two main rotors, but no tail rotor. The main rotors turn in opposite directions. One tries to spin the helicopter one way, while the other does the opposite. They balance each other out, so no tail rotor is needed.

A helicopter can fly up, down, forward, sideways, backward, and even hover in one place.
