

Collecting pollen

Insects such as bees visit flowers to drink nectar and collect pollen. As the insects crawl on the flower, some pollen grains from the anthers stick to their bodies and legs. When the bees visit other flowers, this pollen rubs off on their stigmas.

Pollen

The Queen of the Andes is a South American plant that flowers after 80–150 years and then dies.

Sweet food

Nectar is made at the bottom of the flower. Insects crawl inside to reach the sweet, sugary liquid.

Ovary

Inside the flower.....

The ovary contains the plant's eggs. Pollen that collects on the stigma comes down the style to join with the eggs and grow into seeds.

Quick quiz

Which part of a flower produces the pollen?

Why do insects visit flowers?

Where is nectar made?
