

Animal groups

Frogs, newts, and wormlike creatures called caecilians make up the three groups of animals called amphibians. Like frogs, the young of these animals hatch from eggs and look very different from the full-grown adults.

5 Living on land

By four months, frogs are fully grown, with strong back legs, which help them to swim, climb, and leap on land. Adult frogs will return to the water to find a mate and lay eggs.

4 Breathing air

After three months, tadpoles grow lungs to breathe air from the surface of the water. They also grow front legs and their tails start to shrivel up.

Quick quiz

Where do frogs lay their eggs?

When do tadpoles grow back legs?

When do tadpoles lose their tails?
