

Plant protection

Plants have many ways to defend themselves from being trampled or eaten. Some have built-in protection, such as thorns. Other plants might form a partnership with animals.

They can't run away from predators!

A large photograph of a giraffe with its characteristic brown and white patterned coat, reaching its long neck up to eat green leaves from a tree. The tree has prominent, sharp, reddish-brown thorns. A line points from the text to one of these thorns.

The tree's spiky thorns do not stop the giraffe from having a good chew.

Sharp taste

Ants live inside the thorns of acacia trees, safe from predators. In return, they protect the tree by biting the tongues of animals eating the tree.
