

Meat-eaters

Not all plants feed on sunlight and water alone – some add meat to their diet to give them extra nutrients. There are four main ways meat-eating, or carnivorous, plants catch their prey.

This one got away!

It's a trap!

Tiny hairs inside the leaves of a Venus fly trap can sense when an insect has landed. If two or more hairs are touched together... SNAP! It slams shut.

Digesting cells

When an insect has been caught, glands on the inside of the trap get to work. They release a kind of acid that starts to digest the insect.

The insect inside this Venus fly trap is being prepared for lunch.
