

AVERTION

In classical physics, the nature of a system at any point in time can be precisely calculated using deterministic rules, such as Isaac Newton's laws of mechanics. In the quantum world, however, systems unravel unpredictably. A quantum system is best described with mathematical "wave function," which gives the probability of finding it in a certain state at a certain time. Quantum systems that could be in one of several states can be described with a superposition of all these possible states, although this superposition always "collapses" into a single state when a measurement is taken. It is this collapse of the wave function that creates unpredictability.
