

INSTANT COLLAPSE

When a quantum system is measured, the wave function (see pp.36–37) representing the superposition of states, with probabilities assigned to different states, stops evolving and is reduced to a single definite state. This process is known as wave function collapse. The evolution of the wave function is determined by the Schrödinger wave equation (see pp.44–45); at any specific point in time, wave function collapse leaves only one possible outcome.
