

THE OBSERVER'S BELIEF

Named after 18th-century statistician Thomas Bayes, and also known as QBism (pronounced “cubism”), this interpretation of quantum physics puts the observer at the center of the theory. In the same way that Bayesian statistics allow people to adjust their ideas about the likelihood of events as more information becomes available, so according to QBism, the wave function is merely a representation of the observer’s subjective information and beliefs about possible different outcomes.

All in the mind

Quantum Bayesianism relies on arguments that the entire concept of probability is a mental construct rather than an objective property of reality.
