

How do we find the holes?

Scientists can find black holes because gas and dust falling into a hole rub together and become incredibly hot. This gives off X-rays, which space telescopes detect.

This X-ray picture shows a black hole (the blue dot) at the centre of a galaxy, with a mass 30 million times that of our Sun. The orange dots are just black holes eating stars that got too close.

Later, the black hole's gravity would pull harder on the astronaut's feet than at their head.

The astronaut would be stretched into a long, thin, spaghetti-like shape, finally being crushed to an invisible speck.

If an astronaut entered a black hole, at first he or she wouldn't notice.

Is that true?

Some people think a black hole may be a doorway to another universe. But it's all just speculation. Nobody really knows. However, it is doubtful someone could survive the journey through the hole to find out. An astronaut unfortunate enough to try would be stretched out like a piece of spaghetti.
