

The Universe

A typical galaxy contains
over 100,000 million stars.

The Universe includes the Earth and its moon, the Sun and the solar system, the Milky Way, the galaxies we know, and the galaxies we haven't yet discovered.

That's big...

The galaxies are spread over such unimaginable distances that even a space probe would take two billion years to cross our galaxy.

... and getting bigger

The Universe is still expanding, so all the galaxies are moving farther and farther apart.
