

Diameter: 3,130 km (1,945 miles)

False colour  
image of Europa

Europa is not striped with red! False colour images, such as this one of Europa's lines, are helpful as they show features very clearly.

**Europa** has an icy surface criss-crossed with lines that suggest deeper activity. Scientists believe the ice covers a layer of liquid salty water – a huge ocean, with a possibility of aquatic life. In fact, it has become the most likely place for extraterrestrial life in our solar system.

Diameter: 5,268 km (3,273 miles)

Ganymede is the largest known moon in our solar system.

**Ganymede** is larger than Mercury, but is not a planet because it doesn't orbit the Sun. Scientists think this moon has a molten core, surrounded by a rocky mantle, possible salt water, and an ice shell.

Diameter: 3,643 km (2,264 miles)

Volcano  
erupting

Material is thrown a long way into space by Io's volcanoes.

**Io** is constantly undergoing volcanic eruptions across its surface, resulting in its amazing yellow-orange colour. In fact, it has more than 100 active volcanoes! The eruptions happen because this moon is continually tugged and pushed around by the gravities of Jupiter and the other three moons.

Diameter: 4,806 km (2,986 miles)

Callisto is incredibly battered, the result of thousands of meteorite strikes.

**Callisto's** dark, dirty, and icy crust is covered with craters. The largest, Valhalla, has shockwaves that spread out some 3,000 km (1,865 miles). Astronomers believe the crust hides a rocky core.
