

Saturn

Saturn is the second-largest planet in our solar system. It is huge. You could line up nine Earths in a row across Saturn, but as it is largely composed of gas, you couldn't land a craft on its surface.

Saturn is the sixth planet from the Sun in the solar system.

A ringed beauty

Saturn isn't the only planet with rings, but it is the only planet whose rings are easily visible to us because of their large area. The rings are made up of ice, dust, and rock.

Ice in Saturn's rings reflects light. That's why we see them so well.

Saturn spins around once every 10 hours 39 minutes, making it bulge at the middle as it spins.

Saturn is named after...

Blown away

Even if you could land on Saturn, you'd be blown away pretty quickly by the incredibly strong winds. Winds around the planet's equator can reach 1,800 km (1,100 miles) an hour.

High winds on the Earth would be very light winds on Saturn.
