

MOTHS

Most moths are night-fliers, and their strong senses of smell and hearing make them well suited to a nighttime existence. They can easily find their way through darkness and although attracted to light, they are dazed by it. Moths rest by day, and many are colored to look like tree bark or leaves so that they cannot be spotted by natural enemies such as birds and lizards.

The South American ghost moth has one of the biggest wingspans of any moth. Wingtip to wingtip, it can measure up to 12 inches (30 centimeters).

Nymphalid butterfly

Wings at rest

One way to tell a moth from a butterfly is to see how the insect folds its wings. Most moths rest with their wings folded over their backs. But butterflies close their wings upright.

White ermine moth

Moths' antennae are straight or fernlike. They are used for smelling out nectar or other moths at night.

A moth's body is thick and strong.

A moth's wings are joined together.
