

Different brains

Animals have brains of various shapes and sizes, suited to the things they do.

The occipital lobe is connected with your sense of sight. It helps control eye movement, makes sense of what you see, and allows you to remember things that you've seen before.

Brain relay

When you want to touch something, a signal is passed from your brain to other parts of your body like a baton in a relay race. It goes first to the spinal nerves then to the motor nerves, which tell muscles to move.
