

FORCE AND MOVEMENT

A rocket can only take off because a blast of energy forces it to move. Things move if they are pushed or pulled, or if they are high up to start with. The movement they make has a speed in a particular direction.

How quickly they speed up depends on how big the force is, and how heavy the moving thing is. Some forces make things move, but others stop things from moving. Friction is the name for the force that stops movement.

Roll apart

If one girl pushes the other, both will start to roll away from each other. When a force pushes one way, another force pushes equally in the opposite direction.

The go-cart wheels will keep moving until something stops them or slows them down.

The heavier the passenger is, the more difficult it is to push the go-cart along and make it speed up.

Push it!

Pull it!

Squeeze it!

Playing with force

Forces can act in lots of different directions to change the shape of something. Try

this for yourself with a lump of modeling clay.
