

Special collection

When a hummingbird pushes its long beak deep inside the flower to collect the nectar, some pollen brushes off onto its body.

Inside story

Not many insects would ever find the flowers of the fig tree. They actually grow inside the figs! They are pollinated by special fig wasps that live inside the fig. When the flowers are producing pollen, some of the wasps leave home. They move into another fig, carrying pollen with them on their bodies.

Tropical favorite

The bird of paradise flower grows in the tropics. It is pollinated by bats as well as by birds.

Pollen is brushed onto the bat's fur as it moves from flower to flower.

The bat's long tongue is perfect for whisking out the nectar.

On its nightly nectar hunt, one bat can pollinate several flowers.

Bats find it easy to pick out the spiky shape of the bird of paradise flower at night.
