

A sea of grass

Most plants grow from the top, but grass grows from the bottom. This means it can grow back if it's eaten, or if it is flattened by being trampled.

Grass
shedding seed

Grass seed

Grass plants use the wind to spread their pollen (the fine dust that passes from male flowers to female flowers) and their seeds.

In summer, clouds of grass pollen give some people hay fever.

Grass is resistant to being trampled by hooves.

The cycle of life

Tropical grasslands have wet and dry seasons. In the dry season, the grass turns straw-coloured and dies. With the rainy season, it springs back to life.
