

Bright

Dark

Light enters your eyes through your pupils (the black circles in the middle). Pupils can change size. When it's dark they get bigger to let more light in, and when it's bright they shrink so you don't get dazzled.

How your eye works

The human eye works like a camera. The front parts of the eye focus light rays just as a camera lens does. The focused rays form an upside-down image in the back of your eyeball.

Reflecting light

When light hits a mirror, it bounces straight back off. If you look into a mirror, you see this bounced light as a reflection.

Convex mirrors bulge outwards. They make things look smaller but let you see a wider area.

Concave mirrors bulge inwards. They make things look bigger but show a smaller area.

Light beams

Unless it enters your eyes, light is invisible.

The beam of light from a lighthouse can only be seen from the side if it catches mist or dust in the air, causing some of the light rays to bounce off towards you.

Lighthouse beams sweep round in circles and can be seen from far out at sea.
