

Although the constellations look small on this map, they are very large in the sky.

In the course of one night, the constellations change their position in the sky. One star—Polaris—stays still, while the other stars circle around it.

Polaris is here in places at 45° north, such as Toronto in Canada.

Finding Polaris

To find Polaris, ask an adult for the latitude of your home. Face north using your compass.

Hold your arm horizontally in front of you and move it up the same amount of degrees as your latitude.

Your arm will point to Polaris.
