

Moon moves

Everything in the sky moves. The Moon follows a path across the sky, and if you look at it from time to time one evening, you'll see how its position changes. In this view (left), less than one hour has passed between the top and bottom Moons.

Gibbous—when the Moon gets “smaller,” it is said to be waning.

Full Moon—
all of the side
facing us is lit up.

Gibbous—three-quarters is visible. The “growing” Moon is said to be waxing.

PHASE YOURSELF

You can create the phases of the Moon yourself. You will need a flashlight, silver foil, and a large round object, such as an apple. Use the silver foil to make a ball the size of a golf ball—this is your “Moon.” The apple is your “Earth,” and the flashlight is your “Sun.”

1. Place the Earth and Moon on a table, with the Sun an arm's length away.
2. Move the Moon around the Earth. Stay in the same place as you do this. You'll see that different lit parts of the Moon—its phases—come in and out of view.
